

Non-Life Insurance: Mathematics and Statistics

Exercise sheet 6

Exercise 6.1 Goodness-of-Fit Test

Suppose we are given the following claim size data (in increasing order) coming from independent realizations of an unknown claim size distribution:

210, 215, 228, 232, 303, 327, 344, 360, 365, 379, 402, 413, 437, 481, 521, 593, 611, 677, 910, 1623.

Use the intervals

$$I_1 = [200, 239), \quad I_2 = [239, 301), \quad I_3 = [301, 416), \quad I_4 = [416, 725), \quad I_5 = [725, +\infty)$$

to perform a χ^2 -goodness-of-fit test at significance level of 5% to test the null hypothesis of having a Pareto distribution with threshold $\theta = 200$ and tail index $\alpha = 1.25$ as claim size distribution.

Exercise 6.2 Log-Normal Distribution and Deductible

Assume that the total claim amount

$$S = \sum_{i=1}^N Y_i$$

in a given line of business has a compound distribution with $\mathbb{E}[N] = \lambda v$, where λ denotes the claims frequency, and with a log-normal distribution with mean parameter $\mu \in \mathbb{R}$ and variance parameter $\sigma^2 > 0$ as claim size distribution.

(a) Show that

$$\begin{aligned} \mathbb{E}[Y_1] &= \exp \left\{ \mu + \frac{\sigma^2}{2} \right\}, \\ \text{Var}(Y_1) &= \exp \{ 2\mu + \sigma^2 \} (\exp \{ \sigma^2 \} - 1) \quad \text{and} \\ \text{Vco}(Y_1) &= \sqrt{\exp \{ \sigma^2 \} - 1}. \end{aligned}$$

Hint: Use the moment generating function of a Gaussian distribution with mean μ and variance σ^2 .

(b) Suppose that $\mathbb{E}[Y_1] = 3'000$ and $\text{Vco}(Y_1) = 4$. Up to now, the insurance company was not offering contracts with deductibles. Now it wants to offer a deductible of $d = 500$. Answer the following questions:

- (i) How does the claims frequency λ change by the introduction of the deductible?
- (ii) How does the expected claim size $\mathbb{E}[Y_1]$ change by the introduction of the deductible?
- (iii) How does the expected total claim amount $\mathbb{E}[S]$ change by the introduction of the deductible?

Exercise 6.3 Inflation and Deductible

This year's claims in a storm insurance portfolio have been modeled by a Pareto distribution with threshold $\theta > 0$ and tail index $\alpha > 1$. The threshold θ (in CHF) can be understood as deductible, i.e. as the part that the insureds have to pay by themselves. Suppose that the inflation for next year is expected to be $100 \cdot r$ % for some $r > 0$. By how much do we have to increase the deductible θ next year such that the average claim payment remains unchanged?
