

$l-r \geq 1$ . On the other hand

$|\Gamma_p| = |G|^{p-1}$  hence  $p \mid |\Gamma_p|$ , which

implies  $l-r \geq 2$ ; that is there is

$(h, \dots, h) \in \Gamma_p$  with  $h \neq e$  which

proves the lemma.  $\square$

$\square$

8.3.18

Proof of Thm 2.20

Let  $\mathbb{Q} \subset E \subset \mathbb{C}$  be a splitting field of

$f$  and  $R(f) = \{\alpha_1, \dots, \alpha_p\}$  numbered in

such a way that  $\{\alpha_3, \dots, \alpha_p\} \subset \mathbb{R}$ .

~~Now the complex conjugation  $\sigma: \mathbb{C} \rightarrow \mathbb{C}$~~

~~$\alpha_i \mapsto \bar{\alpha}_i$~~

~~fixes  $\alpha_3, \dots, \alpha_p$  and interchanges  $\alpha_1, \alpha_2$ .~~

~~Thus  $\sigma \in \Gamma_E = \Gamma$  and~~

Using lemma II.7 we consider  $G = \text{Gal}(E/\mathbb{Q})$

as a subgroup of  $S_p$ .

- II - 28 -

Notice that the complex conjugation

$\varepsilon: \mathbb{C} \rightarrow \mathbb{C}, z \mapsto \bar{z}$ , fixes  $\alpha_3, \dots, \alpha_n$  and

interchanges  $\alpha_1, \alpha_2$ . Since  $E = \mathbb{Q}(\alpha_1, \dots, \alpha_n)$

this implies  $\varepsilon(E) = E$  and that

$\varepsilon|_E \in \text{Gal}(E/\mathbb{Q}) < S_p$  is the transposition (12).

Since  $f$  is irreducible, Coroll. II.18

implies  $p \mid |\text{Gal}(E/\mathbb{Q})|$  and by Cauchy's

Theorem (Lemma II.21)  $\text{Gal}(E/\mathbb{Q})$

contains an element  $\eta$  of order  $p$ .

Thus  $\eta$  is a  $p$ -cycle (exercise)

and since  $p$  is prime, a transposition

and a  $p$ -cycle generate  $S_p$  (exercise).

□

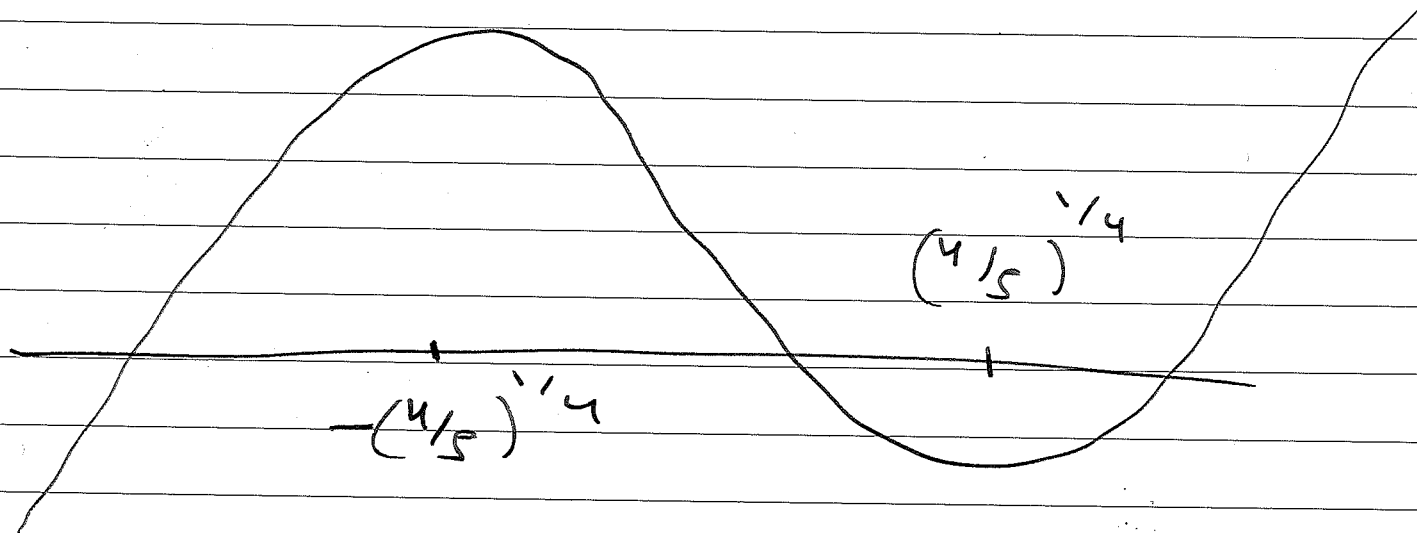

Corollary II.22 The Galois group of  $X^5 - 4x + 2$  is isomorphic to  $S_5$ .

Proof: By Eisenstein's criterion

$$X^5 - 4x + 2 \in \mathbb{Q}[x]$$

is irreducible.

By computing local extrema, we see that the graph of  $f$  has the following shape:

Thus  $f$  has exactly  $3 = 5 - 2$  real zeros and the theorem II.20. applies.  $\square$

The next application of our extension theorem concerns the relation between the transitivity properties of the Galois group of a polynomial as permutation group and the irreducibility of said polynomial.

Corollary II.23 (Prop. A.5.14)

Let  $f \in k[x]$  and  $E$  a splitting field of  $f$ . Assume that  $f$  has no multiple roots. Then

$f$  is irreducible  $\iff \text{Gal}(E/k)$  acts transitively on  $R(f)$ .

Proof:

$(\implies)$  Let  $\alpha, \beta \in R(f) \subset E$ . Applying lemma II.15 to  $\varphi = \text{id}_{kE} : k \rightarrow k$ ,

There is, since  $f$  is irreducible, an isomorphism  $\hat{\varphi}: k(\alpha) \rightarrow k(\beta)$  extending  $\text{id}_k$  and  $\hat{\varphi}(\alpha) = \beta$ .

Now we apply Prop. II.16 to  $f \in k(\alpha)[x]$

and  $\hat{\varphi}: k(\alpha) \rightarrow k(\beta)$  taking into

account that  $\hat{\varphi}(f) = f$  and  $E$  is

a splitting field of  $f$  over  $k(\alpha)$ . We

obtain that  $\hat{\varphi}$  extends to an automorphism

$\sigma: E \rightarrow E$  such that  $\sigma(\alpha) = \beta$  and

$\sigma|_k = \text{id}_k$ ; thus  $\sigma \in \text{Gal}(E/k)$  which

proves  $\Rightarrow$ .

( $\Leftarrow$ ) Conversely assume that  $\text{Gal}(E/k)$

acts transitively on  $R(f)$ . If  $f = p \cdot q$

with  $p, q \in k[x]$ , then  $R(p) \subset R(f)$ ,

$R(q) \subset R(f)$  and  $\text{Gal}(E/k)$  keeps both

$R(p)$  and  $R(q)$  invariant. But  $f$  has no multiple roots, hence  $R(p) \cap R(q) = \phi$  which implies either  $R(p) = \phi$  hence  $p$  is constant or  $R(q) = \phi$  and  $q$  is constant. Hence  $f$  is irreducible.  $\square$

It will be convenient to give a name to splitting fields of polynomials without reference to said polynomial.

Def. II.24 An extension  $E/k$  is normal if it is the splitting field of a polynomial  $f \in k[x]$ .

Remark II.25 Let  $E \supset B \supset k$  be field extensions. If  $E/k$  is normal then  $E/B$  is normal and  $\text{Gal}(E/B) < \text{Gal}(E/k)$ .

We close this chapter with a fundamental result relating the Galois groups of towers of normal extensions.

Thm II.26 (Thm A-5.17)

Let  $k \subset B \subset E$  be extensions such that  $E/k$  and  $B/k$  are normal.

Then for every  $\sigma \in \text{Gal}(E/k)$ ,

$$\sigma|_B = \tau$$

and the surjective homomorphism

$$\text{Gal}(E/k) \rightarrow \text{Gal}(B/k)$$

$$\sigma \mapsto \sigma|_B$$

is surjective with kernel  $\text{Gal}(E/B)$ .

Proof: Let  $f \in k[x]$  such that  $B$

is a splitting field of  $f$ . By lemma II.4

We have for every  $\sigma \in \text{Gal}(E/k)$  that

$$\sigma(R(f)) = R(f) \text{ and since } B = k(R(f))$$

we conclude  $\sigma(B) = B$ . Thus we

obtain a group homomorphism

$$\text{Gal}(E/k) \rightarrow \text{Gal}(B/k),$$

$$\sigma \mapsto \sigma|_B$$

whose kernel is obviously  $\text{Gal}(E/B)$ .

Now we prove surjectivity: let  $g \in k[x]$

such that  $E$  is a splitting field of  $g$

and let  $\sigma \in \text{Gal}(B/k)$ . We apply Prop. IV.16

with  $\sigma: B \rightarrow B$ ,  $f \in B[k]$  and

observe  $\sigma(f) = f$ . Then  $E$  is a splitting

field of  $f \in B[k]$  and Prop. IV.16 gives

an extension of  $\sigma$  to  $\sigma': E \rightarrow E$

with  $\sigma'|_k = \text{id}_k$ , thus  $\sigma' \in \text{Gal}(E/k)$ .  $\square$
